How Radiation Therapy Is Used to Treat Cancer

Radiation is one of the most common treatments for cancer. Other names for radiation treatment are *radiation therapy*, *radiotherapy*, *irradiation*, and *x-ray therapy*.

treatment. Radiation treatments are planned so that they damage cancer cells with as little harm as possible to nearby healthy cells.

Some radiation treatments (systemic radiation therapy) use radioactive substances that are given in a vein or by mouth. Even though this type of radiation does travel throughout the body, the radioactive substance mostly collects in the area of the tumor, so there's still little effect on the rest of the body.

Who gets radiation therapy?

More than half of people with cancer get radiation therapy. Sometimes, radiation therapy is the only cancer treatment needed and sometimes it's used with other types of treatment. The decision to use radiation therapy depends on the type and stage of cancer, and other health problems a patient might have.

What are the goals of radiation therapy?

Most types of radiation therapy don't reach all parts of the body, which means they're not helpful in treating cancer that has spread to many places within the body. Still, radiation therapy can be used to treat many types of cancer either alone or in combination with other treatments. While it's important to remember each cancer and each person is different, radiation is often the treatment of choice for the following purposes.

To cure or shrink early-stage cancer

Some cancers are very sensitive to radiation. Radiation may be used by itself in these cases to make the cancer shrink or completely go away. In some cases, chemotherapy or other anti-cancer drugs may be given first. For other cancers, radiation may be used before surgery to shrink the tumor (this is called *pre-operative therapy* or *neoadjuvant therapy*), or after [surgery](#)² to help keep the cancer from coming back (called *adjuvant therapy*).

For certain cancers that can be cured either by radiation or by surgery, radiation may be the preferred treatment. This is because radiation can cause less damage and the part of the body involved may be more likely to work the way it should after treatment.

For some types of cancer, radiation and chemotherapy or other types of anti-cancer drugs might be used together. Certain drugs (called *radiosensitizers*) help radiation work better by making cancer cells more sensitive to radiation. Research has shown

that when anti-cancer drugs and radiation are given together for certain types of cancer, they can help each other work even better than if they were given alone. One drawback, though, is that side effects are often worse when they are given together.

To stop cancer from coming back (recurring) somewhere else

Cancer can spread from where it started to other body parts. Doctors often assume that a few cancer cells might already have spread even when they can't be seen on imaging scans like CT scans or MRIs. In some cases, the area where the cancer most often spreads to may be treated with radiation to kill them before they grow into other

energy rays from outside the body into the tumor. It's done during outpatient visits to a hospital or treatment center. It's usually given over many weeks and sometimes will be given twice a day for several weeks. A person receiving external radiation is not radioactive and does not have to follow special safety precautions at home.

You may also need the services of a dietitian, physical therapist, social worker, dentist or dental oncologist, pharmacist, or other health care providers.

Does radiation therapy cause cancer?

It has long been known that radiation therapy can slightly raise the risk of getting another cancer. It's one of the possible side effects of treatment that doctors have to think about when they weigh the benefits and risks of each treatment. For the most part, the risk of a second cancer from these treatments is small and is outweighed by the

radiation therapy. There is no clear research about how sperm that is exposed to radiation affects future children made from that sperm. If you are thinking about radiation therapy that will affect the testicles, talk to your doctor about how this might affect having children in the future.

Questions to ask about radiation therapy

Before treatment, you'll be asked to sign a consent form saying that your doctor has explained how radiation therapy may help, the possible risks, the type of radiation to be used, and your other treatment options. Before signing the consent form, be sure that you have had a chance to get all your questions answered. Here are some of the things you may want to ask about:

- What's the purpose of radiation treatment for my type of cancer? To destroy or shrink the tumor? To prevent or stop cancer spread? To lower the chance the cancer may come back?
- What's the chance that the cancer will spread or come back if I do – or don't – get radiation therapy?
- What type of radiation therapy will I get?
- Are there other treatment options?
- What can I do to be ready for treatment?

- What long-term side effects might I have?
- Will I be at higher risk for any other health problems in the future?
- Will I be radioactive during or after my treatment?
- Are any special precautions needed during or after my treatment?
